Power-Preserving Interconnection of Single- and Two-Phase Flow Models for Managed Pressure Drilling*

M.H. Abbasi¹, H. Bansal¹, H. Zwart²,³, L. Iapichino¹, W.H.A. Schilders¹, N. van de Wouw²,⁴

Abstract—Many complex systems are modeled by a network of different subsystems, each having their underlying mathematical model representations. Energy-based modeling of each of these subsystems can yield a port-Hamiltonian (pH) representation. In this paper, a single-phase flow model, a dissipative mathematical component and a two-phase flow model are interconnected to model hydraulics for Managed Pressure Drilling (MPD) applications. These subsystems are interconnected in a power-preserving manner to build an aggregated pH system for real-life MPD scenarios. We prove that the interconnection junction connecting the single- and two-phase flow models is conditionally power-preserving.

I. INTRODUCTION

Port-Hamiltonian (pH) systems have recently received a lot of attention for modeling physical phenomena governed by nonlinear Partial Differential Equations (PDEs) and ordinary differential equations [5], [16]. A pH realization offers a suitable description of the components for the modeling, analysis and controller design [5].

Controllers for PDEs are generally designed for finite-dimensional state-space model descriptions obtained after a low-resolution spatial discretization of the PDEs, which lack part of the information (such as mass conservation) present in the infinite-dimensional representation. Next to PDE control techniques such as optimal control, backstepping [8] and adjoint methods [12], recently, researchers have been investigating control strategies for pH representations [5]. A pH framework enables controller design based on energy consideration by different techniques such as energy-shaping [10], and interconnection and damping assignment [14]. In addition, the Hamiltonian defined in pH framework represents a good candidate for the Lyapunov function, rendering the physics-based control design and the stability proof more tangible [11].

One interesting feature of pH systems is power preservation. A key property of pH systems is that the interconnection

of such systems still preserve the pH structure if the interconnection is performed in a power-preserving manner [5], [3]. This compositional feature enables to interconnect the individual pH subsystems to define an aggregated pH system. A lot of work has already been done in the past in the scope of integration of finite-dimensional and infinite-dimensional components [5], [3]. The key point in aggregating different pH subsystems is the identification of the interconnection structure and casting this interconnection into a power-preserving structure.

Hydraulics in an Managed Pressure Drilling (MPD) can be characterized by interconnection of subsystems governed by a single-phase flow in one pipe and a two-phase flow in another pipe (see Figure 1), and, mathematical models governed by nonlinear ordinary differential equations or static equations [1]. A single-phase flow is usually modelled by the isothermal Euler equations, which obeys a pH formalism [4]. For two-phase flow modelling, the Two-Fluid Model (TFM) and the Drift Flux Model (DFM) are typically employed [1]. Recently, it has been shown that the TFM and a DFM without slippage between the two phases can also be cast in the pH formalism [2]. Drilling with MPD is composed of single- and two-phase flow pH realizations, which can be interconnected via MPD equipment (bit) in a power-preserving manner to form an aggregated pH system.

We employ the existing theory to interconnect (individual) mathematical subsystem models to construct an aggregated model for MPD. To the best of our knowledge, compositional pH modeling for MPD is taken up for the first time in this paper. A compositional pH representation of the MPD model is useful when it needs to be connected to other systems such as a reservoir model, where each system is characterized by a particular energy property. The compositional structure, presented in this work, can be viewed as a stepping stone towards a holistic control paradigm for MPD scenarios. To the best of our knowledge, most controllers for MPD are designed based on a lumped-parameter models approximating the hydraulics and ignoring the fast pressure dynamics [1]. The framework introduced in this paper enables an energy-based controller design while taking all (infinite-dimensional) dynamics into account.

The contribution of this study is two-fold. First, a power-preserving interconnection at the junction connecting the single- and two-phase flow models are provided and, second, a power-preserving condition for a typical junction used in MPD [13] interconnecting these two models is derived. Outside this conditional power-preserving region, the interconnection junction generates power, which renders the
junction model (that connects the two subsystems) non-physical.

The structure of this paper is as follows. In Section II, a brief introduction to MPD is provided. In Section III, single- and two-phase flow models together with their pH formalisms are introduced. In Section IV, the interconnection of the single- and two-phase flow models together with the conditional power preservation of the interconnection junction is discussed. In Section V, the power-preserving interconnection of the systems in a real-life drilling scenario is investigated. Finally, Section VI concludes the paper.

II. MANAGED PRESSURE DRILLING

The industrial problem under investigation is a drilling system, with a special focus on MPD. The configuration of the system is illustrated in Figure 1. A drilling liquid known as mud is pumped into a pipe, called the drillstring, at high pressure. At the bottom of the drillstring, the mud leaves the drillstring through nozzles created inside the drill bit and enters the area between the drillstring and the wellbore, known as the annulus. It then flows up through the annulus and carries the rock cuttings out of the well. In MPD, the annulus is sealed off from the surroundings at the top with a Rotating Control Device (RCD in Figure 1) and the mud circulates out of the well through a choke valve. The circulation path of the mud can be observed by following the green arrows in Figure 1. Usually a flow from the formation containing gas and liquid (this formation is named reservoir in Figure 1) occurs at the bottomhole of the annulus, leading to multi-phase flow in the annulus. For a more comprehensive explanation of MPD, single-phase and two-phase flow modeling, we refer to [13].

Remark 1: If no contingency happens during drilling, the flows inside the drillstring and annulus are of a single-phase flow nature. In case of liquid influx, we assume the reservoir produces the same liquid as the drilling mud. If a gas influx occurs in the formation, the flow inside only the annulus involves two phases.

Notation: The following short-hand notations are used in the paper. \( x_a, x_d \): spatial coordinate in the annulus and drillstring, \( x_d \in \Omega_d = [0, L] \) and \( x_a \in \Omega_a = [0, L] \): spatial domain in the drillstring and annulus, respectively. \( \partial_{x_d} , \partial_{x_a} \): variable (·) by the boundary \( x_d = L \), \( \partial_{\Omega_a} \): the i-th component of the decomposed variable (·) at the boundary \( x_a = 0 \), \( \partial_{L_d} , \partial_{\Omega_d} \): variable (·) at \( x_d = L \), \( \partial_{\Omega_d} \): boundary variables at the reservoir for the gas and liquid phase, respectively. Subscripts \( \partial_{x_d} \) and \( \partial_{\Omega_d} \) refer to the values for liquid and gaseous phase, respectively. \( \mathbb{R} \) denotes the space of real numbers.

III. PORT-HAMILTONIAN MODELS

In this section, we briefly introduce the isothermal Euler equations and the TFM. The pH formulation of each of these models is presented in this section. It should be noted that modeling MPD in 1D captures the most important hydraulics features of drilling [1]. Therefore, the governing PDEs and models for the MPD equipment are presented in 1D.

A. Isothermal Euler Equations

Isothermal Euler equations [9] are typically employed to model single-phase flow inside the drillstring [13]. This model encompasses a coupled mass balance and momentum balance equation. For a drillstring with constant cross-sectional area \( A_d \) and a constant inclination of the pipe \( \theta \), see Figure 1, under the assumption of laminar flow, the isothermal Euler equations read as follows:

\[
\partial_t \rho + \partial_{x_d} (\rho v) = 0, \quad (1a) \\
\partial_t (\rho v) + \partial_{x_d} (\rho v^2 + p) = -32\mu t \frac{\partial}{\partial x_d} + \rho g \sin \theta, \quad (1b)
\]

where \( t \in \mathbb{R}_{\geq 0} \) and \( x_d \) denote the temporal and spatial variables in the drillstring, respectively (see Figure 1). Variables \( \rho(t,x_d), v(t,x_d) \) and \( p(t,x_d) \) refer to density, velocity and pressure of the mud inside the drillstring, respectively. Moreover, \( \mu t \) and \( d_A \) denote viscosity of the mud and hydraulic diameter of the drillstring, respectively, and \( g \) is the gravitational acceleration. To complete the set of equations, an Equation of State (EOS) is provided as \( p = (\rho - \rho_0) c_t^2 + p_0 \) with constants \( \rho_0 \) and \( p_0 \) (respectively the density and pressure around which the EOS is linearized), and \( c_t \) being the speed of sound in the mud.

The Hamiltonian function for (1) in the state variables \( z := [\rho, v]^T \) is

\[
\mathcal{H}(z) := A_d \int_{\Omega_d} \rho \frac{v^2}{2} + \rho c_t^2 \ln \rho + (c_t^2 \rho_0 - p_0) - \rho g x \sin \theta \, dx.
\]

In the following theorem, the pH formulation corresponding to (1) is introduced.

Theorem 3.1: The governing equations (1) together with the EOS \( p = (\rho - \rho_0) c_t^2 + p_0 \) can be written in the following dissipative pH formulation:

\[
\partial_t z = (J_d - R_d(z)) \delta_t \mathcal{H}(z),
\]

with \( J_d = -\frac{1}{A_d} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \frac{\partial}{\partial x_d} R_d(z) = \begin{bmatrix} 0 & 0 \\ 0 & \frac{-32\mu t}{A_d \rho_0 c_t^2} \end{bmatrix},
\]
where \( z := \begin{bmatrix} \rho, v \end{bmatrix}^T \) and \( H(z) \) is given by (2). This equation is completed by the power conjugated input \( u \) and output \( y \) at the boundaries with coupling relations as follows:
\[
\begin{bmatrix}
\frac{\partial u_{L,a}^B}{\partial t} \\
\frac{\partial u_{L,a}^B}{\partial x_a}
\end{bmatrix} = \begin{bmatrix}
\frac{1}{A_a} \delta_\rho H(z) \\
\delta_v H(z)
\end{bmatrix} \bigg|_{L,a} , \quad \begin{bmatrix}
\frac{\partial y_{0,a}^B}{\partial t} \\
\frac{\partial y_{0,a}^B}{\partial x_a}
\end{bmatrix} = \begin{bmatrix}
-\frac{1}{A_a} \delta_\rho H(z) \\
-\delta_v H(z)
\end{bmatrix} \bigg|_{0,a} .
\]

**Proof:** Using (1a) and the EOS, the momentum equation (1b) can be written in terms of \( \rho \) and \( v \) as
\[
\partial_t v = -\partial_x \left( \frac{\rho^2}{2} + c_t^2 \rho \ln \rho \right) - 32 \frac{\mu v}{d_a^2} + g \sin \theta .
\]
The variational derivatives of \( \delta_\rho H \) is the mass flow rate of the mud passing spatial location \( x_a \) at time \( t \). The energy per unit mass multiplied by the cross section \( A_a \) can be inferred from \( \delta_v H \). Equations in (3) are obtained by a straightforward replacement of \( c_{\delta_e} := \begin{bmatrix} \delta_\rho H, \delta_v H \end{bmatrix}^T \) in (1a) and (5). Boundary conditions (4) are obtained by satisfying the following relation for the time derivative of the Hamiltonian \( H \) and the power through the boundaries of the drillstring \( P^B \).
\[
H + P^B = -\int_{t_a} e^T \delta x_a \bigg|_{L,a} + \frac{1}{A_a} \delta_\rho H(z) \bigg|_{L,a} + \frac{1}{A_a} \delta_v H(z) \bigg|_{L,a} = 0 .
\]

The last inequality is due to the positive semi-definite nature of \( \delta_{\rho \rho} \).

**B. Two-Fluid Model**

The TFM can be defined in terms of PDEs expressing mass and momentum conservation laws for each phase in the annulus with constant cross-sectional area \( A_a \), constant hydraulic diameter \( d_a \), and constant inclination \( \theta \) as follows [15]:
\[
\begin{align*}
\partial_t (\alpha_\ell \rho_\ell) + \partial_x (\alpha_\ell \rho_\ell v_\ell) &= 0 , \\
\partial_t (\alpha_g \rho_g) + \partial_x (\alpha_g \rho_g v_g) &= -\partial_x (\alpha_{\ell g} v_\ell v_g) + M_{\ell g} \alpha_{\ell g} v_\ell \ln \rho_\ell - 32 \frac{\mu_\ell_\ell v_\ell}{d_a^2} ,
\end{align*}
\]
where \( i \in \{ \ell, g \} \) and \( x_a \) is the spatial variable in the annulus (see Figure 1). The model contains seven unknown variables, namely, liquid and gas void fraction, \( \alpha_\ell \) and \( \alpha_g \), liquid and gas phase velocity, \( v_\ell \) and \( v_g \), liquid and gas phase density, \( \rho_\ell \) and \( \rho_g \), and the common pressure in the annulus \( p_a \). To complete the model, we use a set of widely applied closure laws as in [6]:
\[
\begin{align*}
\alpha_g + \alpha_\ell &= 1 , \\
M_{\ell g} + M_{g \ell} &= 0 , \\
\rho_g &= \frac{p_a}{c_g^2} \rho_\ell + \rho_\ell + \frac{p_a - p_0}{c_\ell^2} ,
\end{align*}
\]
where (9a) expresses that any pipe segment is occupied by the combination of gas and liquid. The terms \( M_{\ell g} \) and \( M_{g \ell} \) with the constant \( c^M \geq 0 \) in (9b) account for the force interaction between the phases. Finally, (9c) define the barotropic EOS of each phase with \( c_\ell \) the constant speed of sound in the gaseous phase.

The Hamiltonian for the flow inside the annulus with \( z_a := \begin{bmatrix} m_g, m_\ell, v_g, v_\ell \end{bmatrix}^T \) takes the following form (with \( m_g := \alpha_\ell \rho_\ell \) and \( m_\ell := \alpha_\ell \rho_\ell \)):
\[
H_a(z_a) := A_a \int \partial_x \frac{v_\ell^2}{2} + \frac{v_g^2}{2} + m_g c_g^2 \ln \rho_g + m_\ell c_\ell^2 \ln \rho_\ell + \alpha_\ell (c_\ell^2 \rho_\ell - p_0) - (m_\ell + m_g) g(L - x_a) \sin \theta \, dx .
\]

Notably, variables \( \rho_\ell, \rho_g, \alpha_\ell \) can be written in terms of \( m_\ell \) and \( m_g \), see [2]. In the following theorem, the pH formulation corresponding to (8) and (9) is presented.

**Theorem 3.2:** The governing equations (8) associated with the closure equations (9) can be written in the dissipative pH formulation as follows:
\[
\begin{align*}
\partial_t z_a &= (J_a - R_a(z_a)) \delta z_a H_a(z_a) , \\
J_a &= \frac{1}{A_a} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} , \quad R_a(z_a) = \frac{1}{A_a} \begin{bmatrix} 0 & 0 \end{bmatrix} ,
\end{align*}
\]

\[
\begin{align*}
\frac{\partial y_{0,a}^B}{\partial t} + \frac{\partial y_{0,a}^B}{\partial x_a} &= \begin{bmatrix}
\frac{\partial y_{0,a}^B}{\partial t} \\
\frac{\partial y_{0,a}^B}{\partial x_a}
\end{bmatrix} \bigg|_{0,a} = \begin{bmatrix}
\frac{\partial y_{0,a}^B}{\partial t} \\
\frac{\partial y_{0,a}^B}{\partial x_a}
\end{bmatrix} \bigg|_{L,a} .
\end{align*}
\]

**Proof:** Rewriting momentum equations (8b) in terms of \( v_g \) and \( v_\ell \) leads to
\[
\partial_t v_\ell + \partial_x \left( \frac{v_\ell^2}{2} \right) = -c_\ell^2 \partial_x (\ln \rho_\ell) \pm \frac{b_\ell}{m_\ell} (v_\ell - v_g) - g \sin \theta - 32 \frac{\mu_\ell v_\ell}{\rho_\ell d_a^2} ,
\]
where “\( - \)“ is used for \( i = g \) and “\( + \)“ is used for \( i = \ell \).
Using the Hamiltonian (10) (for details, see [2]),
\[
\begin{align*}
\delta_{\ell g} H_a &= A_a \int \partial_x \frac{v_\ell^2}{2} + c_\ell^2 \ln \rho_\ell + c_\ell^2 - g(L - x_a) \sin \theta , \\
\delta_g H_a &= A_a m_\ell v_\ell , \quad i \in \{ \ell, g \} .
\end{align*}
\]

Similar to the isothermal Euler equations, \( \delta_g H_a \) represents the mass flow rate of the phase \( i \). Similarly, the energy per unit mass of phase \( i \) multiplied by the cross section \( A_a \) can be inferred from \( \delta_{m_i} H_a \). Straightforward replacement of these relations into the original equations give the asserted equations. Similar to Theorem 3.1, the boundary terms can be obtained from \( (P^B_a) \) is the power through the boundaries.
of annulus) \( \dot{H}_a + \rho_a^B = - \int_{\Omega} e_a R_a e_a \, dx + \left( \frac{1}{A_a} \delta_{mg} H_a \delta_{vg} H_a \right) \big|_{0,a} + \left( \frac{1}{A_a} \delta_{mg} H_a \delta_{vg} H_a \right) \big|_{L,a} - \left( \frac{1}{A_a} \delta_{mg} H_a \delta_{vg} H_a \right) \big|_{0,a} \)

\( y_{L,a} u_{L,a} + y_{L,a} u_{L,a} + y_{L,a} u_{L,a} - \int_{\Omega} e_a R_a e_a \, dx \leq 0 \)

with \( e_a = [\delta_{mg} H_a, \delta_{mg} H_a, \delta_{vg} H_a, \delta_{vg} H_a]^T \).

**Remark 2:** PH properties for the isothermal Euler equations in [4] and the TFM in [2] are proved for only unit cross section without frictional and gravitational source terms. Moreover, a different choice of the state variables than in [2] is employed to express the pH realization of the TFM.

**Remark 3:** It can easily be proved that \( J_d \) in (3) and \( J_a \) in (11) are formally skew-adjoint operators [5]. Moreover, \( R_d \) and \( R_a \) in the same equations are symmetric positive semi-definite.

IV. POWER-PRESERVING INTERCONNECTION

In this section, the drillstring, the drill bit and the annulus are connected in a power-preserving manner. First, the boundary conditions are introduced. Then, the dissipation of energy through the bit is studied. Finally, the power-preserving structure of the interconnection junction (the bit and the summation junction at the reservoir, see Figure 2) is investigated.

A. Boundary conditions of the single- and two-phase flow models in MPD

The boundary conditions governing the fluid flow in the drillstring and the annulus follow from Figure 1. The governing equations of the pump, bit and choke are summarized in Table I. For the pump, \( \dot{m}_p, A_p, \rho_p \) and \( v_p \) represent the mass flow rate, the cross-sectional area, the density and the velocity of the liquid through the pump, respectively. For the bit, \( \Delta \rho_b, \rho_b, \dot{m}_b, A_N \) and \( C_D \) denote the pressure drop over the bit, density at the drillstring side of the bit, the mass flow rate through the bit, the total area of the nozzle of the bit and the nozzle coefficient, respectively. For the choke, \( \dot{m}_c, \rho_c, \rho_p \) and \( p_0 \) are the mass flow rate, the density, the pressure at the choke inlet and atmospheric pressure, respectively. Finally, \( K_c \) and \( z_c \) are the choke constant and the choke opening, respectively.

First, we define the boundary conditions for the drillstring to be used in (4).

<table>
<thead>
<tr>
<th>Equipment</th>
<th>Governing equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pump</td>
<td>( \dot{m}_p = A_p \rho_p v_p )</td>
</tr>
<tr>
<td>Bit</td>
<td>( \Delta \rho_b = \frac{\rho_b}{\rho_b} \left( \frac{\dot{m}_b}{A_N C_D} \right)^2 )</td>
</tr>
<tr>
<td>Choke</td>
<td>( \dot{m}_c = K_c z_c \sqrt{2 \rho_c (v_c - p_0)} )</td>
</tr>
</tbody>
</table>

**Pump:** At the pump location, we have \( A_p = A_d, v_p = v|_{0,a} \) and \( \rho_p = \rho|_{0,a} \). Hence

\[ \delta_v H|_{0,a} = (\delta_v A_d v)|_{0,a} = \dot{m}_p(t). \] (15)

The boundary condition at the left side of the spatial domain \( \Omega \) is assigned. Input and output variables at this boundary can be defined with (15) and (4).

**Bit and reservoir:** Through the bit, the mass conservation holds and the pressure drop is governed by the bit equation. Moreover, the flow that passes through the bit is then mixed with the known liquid mass flow rate \( \dot{m}_b(t) \) and the gaseous mass flow rate \( \dot{m}_g(t) \) coming out of the reservoir. Then, the mixture enters the annulus. Considering \( \Delta \rho_b = \rho|_{L,a} - \rho|_{0,a}, \dot{m}_b = (\rho A_d v)|_{L,a} \), we have

\[ \begin{aligned}
&\left\{ \begin{array}{l}
\rho|_{L,a} - \rho|_{0,a} = \frac{1}{2 \rho|_{L,a} A_N C_D} \\
\delta_v H|_{L,a}^2 + \dot{m}_b(t) = \delta_v H|_{L,a}|_{0,a} \\
\delta_v H|_{L,a}|_{0,a} = \dot{m}_g(t)
\end{array} \right.
\] (16)

**Remark 4:** To solve the TFM, typically either 2 boundary conditions are specified at the left side of the domain and 2 at the right side or 3 boundary conditions at the left side and one at the right [7]. In this paper, we consider the 2-2 case. In (16), one equation corresponds to the right boundary for the isothermal Euler equations in the drillstring and two equations correspond to the left boundary of the TFM in the annulus.

**Remark 5:** Above the bit and inside the drillstring, a non-return valve is installed to restrict the flow in one direction only from the drillstring to the annulus. When this valve is open, the pressure drop over the bit is governed by the bit equation in Table I. When this valve is closed, the drillstring and the annulus become disconnected. Then, the right boundary condition for the drillstring becomes \( \dot{m}_b(t) = (\rho A_d v)|_{L,a} = 0 \) and therefore \( \delta_v H|_{L,a} = 0 \).

The left boundary condition for the annulus changes to \( \delta_v H|_{L,a}|_{0,a} = \dot{m}_b(t) \) and \( \delta_v H|_{L,a}|_{0,a} = \dot{m}_g(t) \).

**Choke:** For the TFM at the choke, we have two boundary conditions, i.e., the explicit value of gas void fraction over time and the nonlinear choke equation. Following the same procedure in [13], we rewrite \( \dot{m}_c \) as the mass flow rate of the mixture, \( \dot{m}_c = (\rho A_a v)|_{L,a} + (\rho B_a v)|_{L,a} \). We also replace \( \rho_c \) with the mixture density, \( \rho_c = \alpha \rho_i + \beta \rho_g \). Therefore, we have:

\[ (\delta_v H + \delta_v H)|_{L,a} = \frac{K_c z_c 2(m_g + m_l)|_{L,a} (p|_{L,a} - p_0)}{\alpha \rho_i = g(t)}, \] (17)

where \( g(t) \) is a function of time, explicitly specifying the gas void fraction at the choke.

**Remark 6:** Notably, boundary conditions (16) and (17) form an implicit function of variational derivative of Hamiltonian (2) and (10) with respect to \( z \) and \( z_a \), respectively.

**Remark 7:** For the case of 2-2 boundary conditions specified above, setting the boundary inputs to zero leads to \( H_x = 0 \) in the absence of dissipation. For the case of 3-1 boundary conditions, setting the boundary inputs to zero will not yield the same result and it is not clear how energy of the system evolves over time. This complicates the energy perspective presented in this paper for 3-1 case.
B. Dissipativity of power through the bit

The power-preserving structure of the single-phase flow model and the TFM are shown in Section III by the corresponding dissipative pH formulation of (3)-(4) and (11)-(12).

In this section, we derive conditions under which the interconnections, shown in Figure 2, are power-preserving. To have power-preserving interconnections, we define the following interconnections between input ports \( u \) and output ports \( y \) of different components shown in Figure 2:

\[
\begin{align*}
\begin{array}{l}
u_d,\text{bit} = \frac{\beta}{u_d,\text{bit}} \quad \nu_a,\text{bit} = \frac{\beta}{u_a,\text{bit}}
\end{array}
\end{align*}
\]

The power preservation of all these connections can be easily checked [5], e.g., \( u_2 y_2 + u_{0,a} y_{0,a} = 0 \). If the power is preserved through the bit, then the entire aggregated system preserves power. Therefore, we only focus on deriving the condition of power preservation through the bit.

Remark 8: Due to the directions shown in Figure 1, the positive direction is assumed from pump to the bit and from the bit to the choke. Therefore, the incoming power into bit flows from the drillstring and the outgoing power from the bit enters the annulus.

The physical nature of the bit dictates the outgoing power to be less than the incoming power (see Figure 2)

\[
P_{\text{bit}} := u_{a,\text{bit}} y_{a,\text{bit}} - u_{d,\text{bit}} y_{d,\text{bit}} \leq 0. \tag{19}
\]

The incoming power \( u_{a,\text{bit}} y_{a,\text{bit}} \) to the model-dependent variables, the power preservation across the summation junction is written as

\[
u_1 y_1 + u_2 y_2 + u_3 y_3 = 0 \quad \tag{18}
\]

Replacing the terms describing the variational derivative of Hamiltonian with respect to state variables from (6) and (14) leads to

\[
\begin{align*}
\frac{\delta^2}{2} + c^2 \ln \left( \frac{\rho}{\rho_0} - gL \sin \theta \right)_{L,d} - \\
\frac{\delta^2}{2} + c^2 \ln \left( \frac{\rho}{\rho_0} - gL \sin \theta \right)_{a,a} \geq 0 \quad \tag{24}
\end{align*}
\]

where \( M_d = \frac{v_{\text{in}}}{c_{\text{ref}}} \), \( M_a = \frac{v_{\text{in}}}{c_{\text{ref}}} \) are the Mach numbers of the flow at the outlet of the drillstring and at the inlet of the annulus near the bit. To further simplify the relation, we use the bit equation,

\[
\Delta p_b = (\rho_{L,d} - \rho_{a,a}) \frac{v_{\text{in}}}{L,d} = \frac{1}{2} \rho_{L,d} \left( \frac{A_d}{A N C D} \right)^2 v_{\text{in}}^2 \rightarrow \quad \tag{25a}
\]

\[
\frac{\rho_{L,d}}{\rho_{a,a}} = 1 - \frac{1}{2} \left( \frac{A_d}{A N C D} \right)^2 M_d^2. \tag{25b}
\]

The mass conservation across the bit (16) can also be simplified to

\[
(A_d \rho v)|_{L,d} + \dot{m}_e(t) = (A_a \rho v_e)|_{a,a} \rightarrow A_d M_d + \dot{m}_e(t) = A_a \frac{\rho v_e}{\rho} M_a \rightarrow M_o = \frac{A_d}{A_a} 1 - \frac{1}{2} \left( \frac{A_d}{A N C D} \right)^2 M_d^2 + M_e, \tag{26}
\]

where \( M_e := \frac{\dot{m}_e(t)}{A_{a,c,D^2} \rho v_e / \rho} \) is the Mach number at the interface of the reservoir and annulus. Finally by using (26), the inequality (24) simplifies to

\[
\mathcal{M} := \frac{1}{2} M_d^2 \left( \frac{A_d}{A_a} 1 - \frac{1}{2} \left( \frac{A_d}{A N C D} \right)^2 M_d^2 + M_e \right)^2 - 1 \quad \tag{27}
\]

For the bit, connecting the drillstring and the annulus, to be power-preserving, the inequality (27) should hold.

V. NUMERICAL EXAMPLE

In this section, a real drilling well is considered and the region where the inequality (27) holds is investigated. The corresponding geometry and bit property are studied to define the power-preserving operational region. Outside this region, the bit model should be adjusted to abide power preservation.

Remark 9: In drilling operations, the velocity inside the drillstring is typically around 1 m/s while the speed of sound in the mud is around 1000 m/s. Therefore, for drilling applications, \( M_d \approx 0.001 \).

The geometry and equipment properties of the drilling platform are given by

\[
d_d = 76.2 \text{ mm}, \quad d_{ad} = 241.3 \text{ mm}, \quad d_w = 444.5 \text{ mm}, \quad A_N = 1418.7 \text{ mm}^2, \quad C_D = 0.8, \tag{28}
\]

![Fig. 2. The power-preserving interconnection of different components of a drilling well.](image-url)
where \( d_{od} \) and \( d_{uw} \) are, respectively, the outer diameter of the drillstring and the diameter of the wellbore.

For this well and this drill bit, to render the argument inside the logarithmic function in (27) to be positive, we observe that \( M_d < 0.35 \) should hold. As shown in the top part of Figure 3, in this restricted region for \( M_d \) with no flow from the reservoir (which is true in the normal drilling scenarios), (27) always holds for \( \dot{\nu}_d = 0 \) for the drilling well under consideration and the bit model is indeed dissipative (power-preserving). This might be the experimental condition under which the model for the bit was derived.

In case of contingencies, where the fluid of the reservoir flows into the annulus, condition (27) is not always satisfied in the restricted region for \( M_d \), as shown in the bottom part of Figure 3. When the reservoir also contains liquid, the velocity of this flow should be less than the velocity of the liquid influx from the reservoir flows into the wellbore. In such cases, velocity of the drilling mud at the bit inside the annulus should be higher than the velocity of the liquid influx. Outside this region, the power preservation of the bit model might be violated. The framework proposed in this paper enables an energy-based controller design for MPD while taking the infinite-dimensional nature of the dynamics into account.

VI. Conclusion

In this paper, two \( \text{pH} \) models for the (single- and two-phase) flow dynamics in MPD with nonlinear boundary conditions are interconnected by a nonlinear drill bit model. To render the aggregated system power-preserving, the mathematical model of the bit, used to interconnect the two pipes, obeys power preservation under a certain condition. However, this conditional power preservation does not restrict the normal drilling operation region. The drill bit model restricts the drilling operation where liquid influx from the reservoir flows into the wellbore. Therefore, the bit model presented in this paper enables an energy-based controller design for MPD while taking the infinite-dimensional nature of the dynamics into account.
